- Deep RL
- Examples of RL for NLP

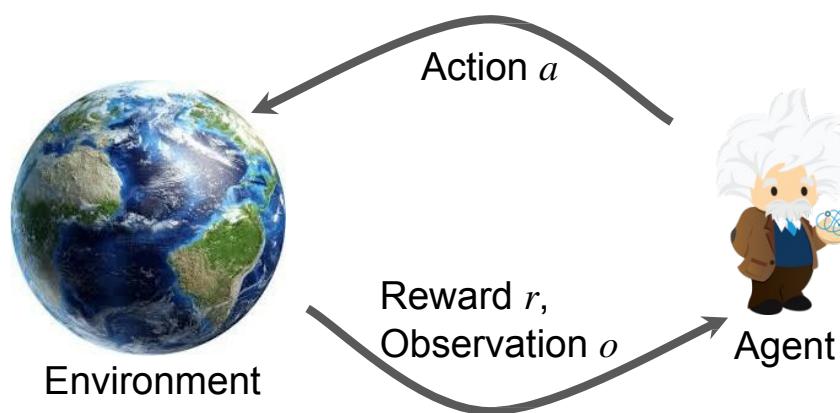

# Many Faces of RL

By David Silver

# What is RL?

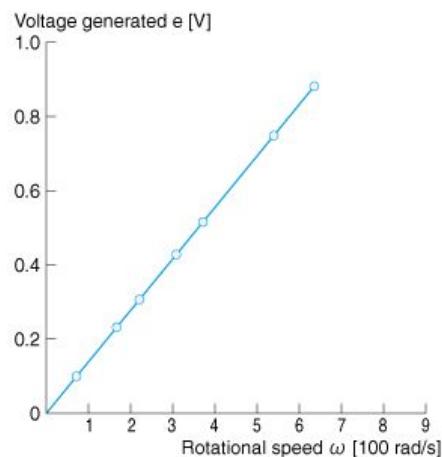

- RL is a general-purpose framework for **sequential** decision-making
- Usually describe as agent interacting with unknown environment
- Goal: select action to **maximize a future cumulative reward**

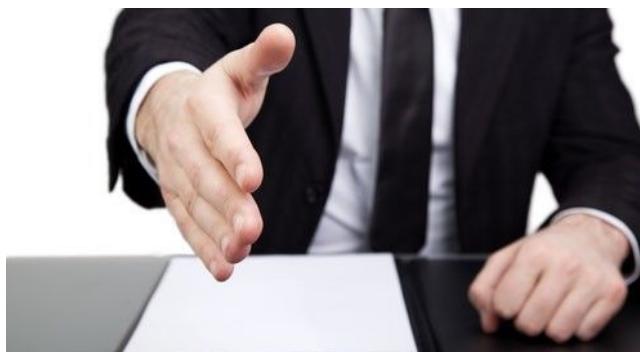

# Environment

- Agent learns **mapping** from situations to actions.
  - By trial-and-error interactions with dynamic environment
- Environment must be at least **partially observable** by RL system.
- Observations may be low level, high level or “mental”.

**Voltage**

**Accept job offer**

**Shift in attention**

# Motor Control

- Observations: images from camera, joint angle
- Actions: joint torques
- Rewards: navigate to target location, serve and protect humans

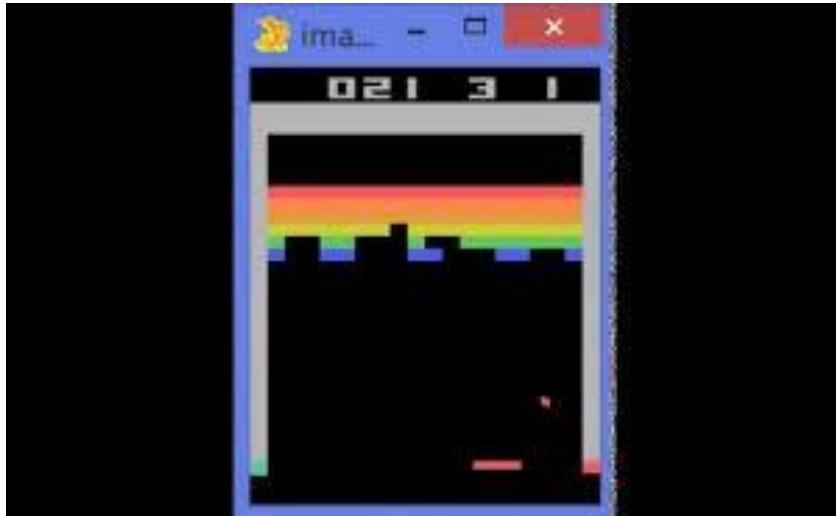

# Business Management

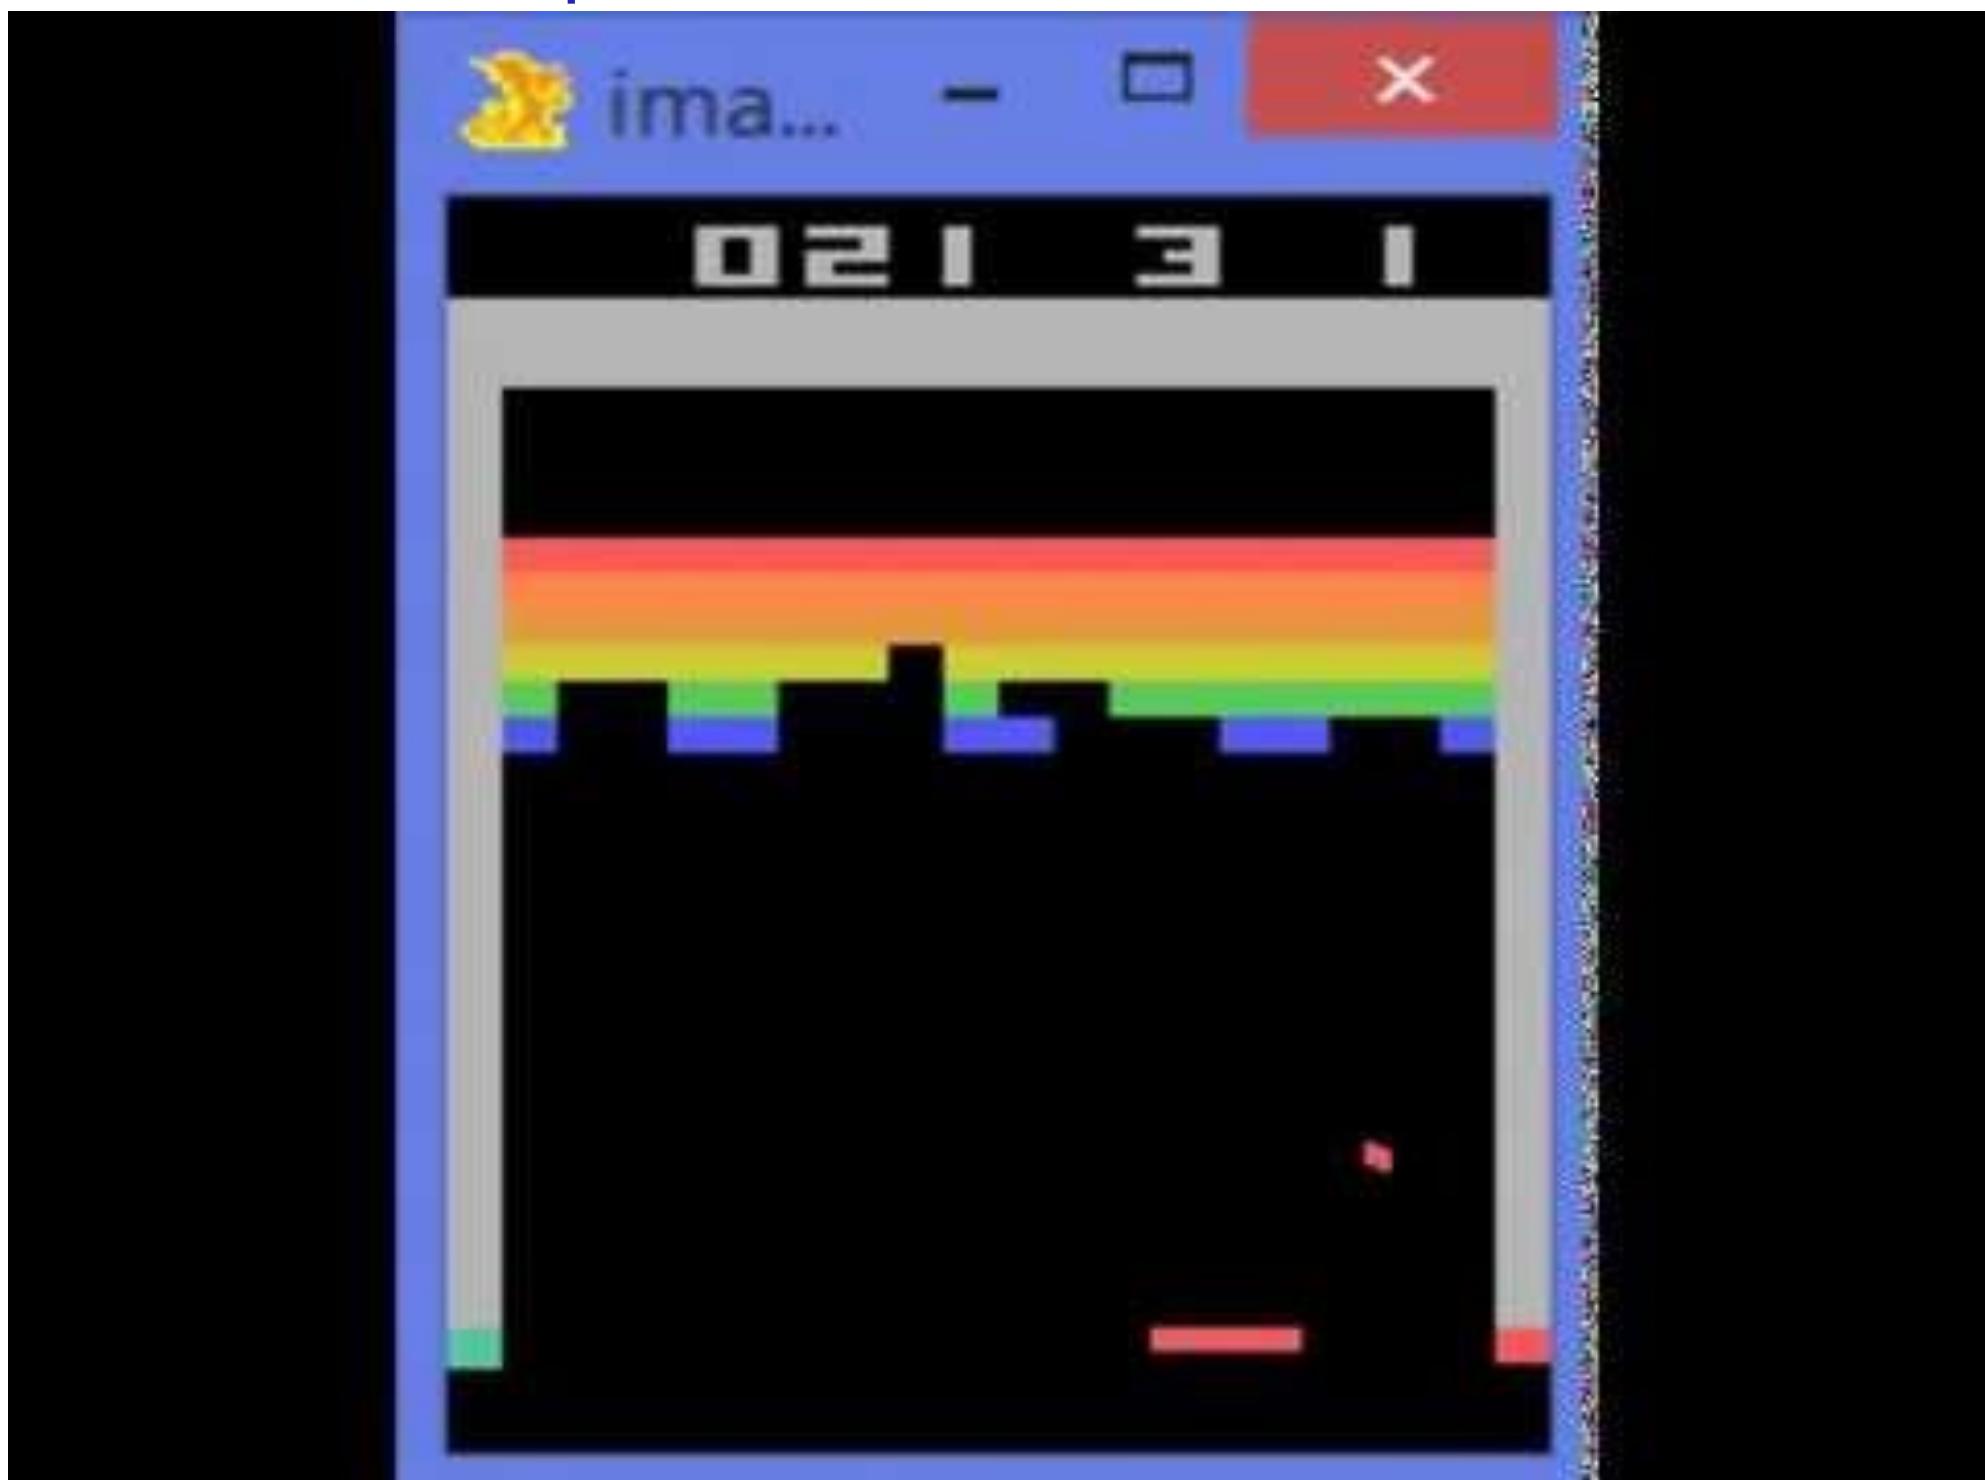

- Observations: current inventory levels and sales history
- Actions: number of units of each product to purchase
- Rewards: future profit

Similarly, there also are resource allocation and routing problems ....

# Games

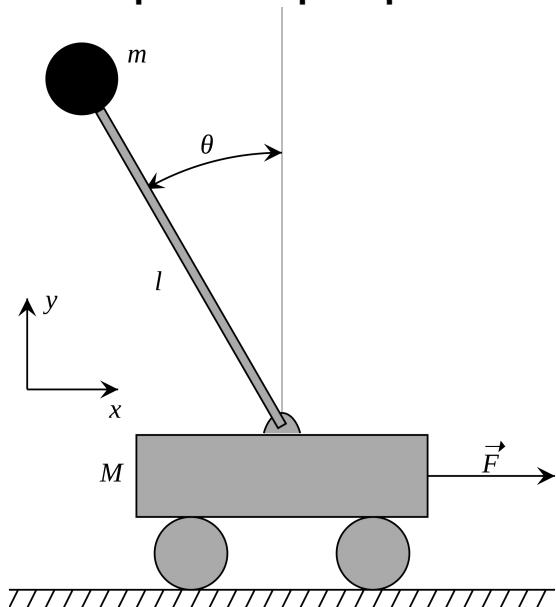

# Two Minute Papers

# Reinforcement Function

- “Goal” of RL system
- Function of **future reinforcements(rewards)** agent seeks to maximise.
- i.e. Exists mapping from state-action pairs to reinforcements.
  - After performing an **action given a state**, agent receives a **scalar value**.

Example: Cart-pole problem

## Pure Delayed Reward Reinforcement Function

- Goal: Balance pendulum
- State: Dynamic state of pole system
- Actions: Left or right
- Reinforcement function:
  - -1 if pole falls
  - 0 everywhere else
- Agent will learn sequence of actions to balance pole and avoid -1 reinforcement.

# State

- Experience is a sequence of observations, actions, rewards
- The state is a summary of experience

$$s_t = f(o_1, r_1, a_1, \dots, a_{t-1}, o_t, r_t)$$

# RL Agent

Major components:

- Policy: agent's behavior function
  - Mapping of **states to actions**
- Value function: how good would each state and/or action be
  - **Sum of reinforcements** received from that state and **following a fixed policy** to a terminal state.
- Model: agent's prediction/representation of the environment

# Policy

A function that maps from state to action:

- Deterministic policy:

$$a = \pi(s)$$

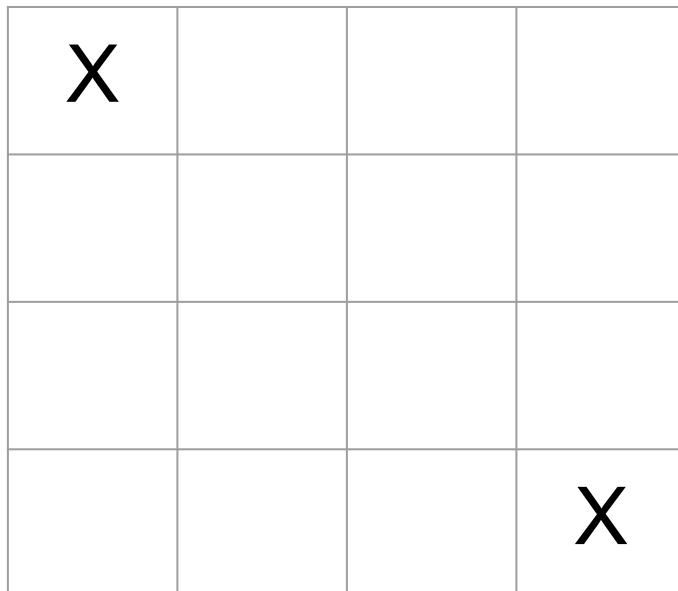

- Stochastic policy:

$$\pi(a|s) = \mathbb{P}[a|s]$$

# Example of Value Function

Simple Markov Decision Process with 16 States

State space

- Each square represents a state
- Reinforcement function is -1 everywhere
  - -1 reinforcement per transition
- 4 Actions: Left, right, up, down
- Goal states: Upper left & Bottom right

# Example of Value Function

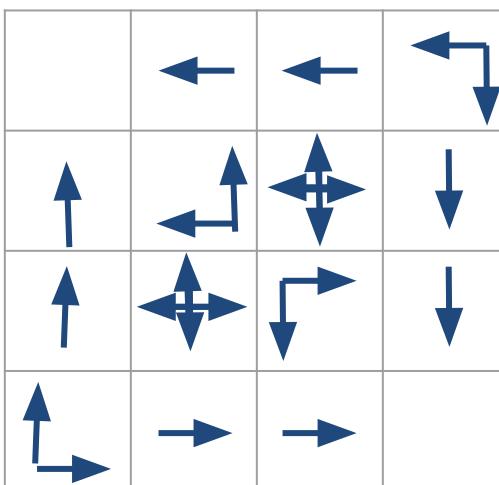

Value function of **random** policy

|     |     |     |     |
|-----|-----|-----|-----|
| 0   | -14 | -20 | -22 |
| -14 | -18 | -22 | -20 |
| -20 | -22 | -18 | -14 |
| -22 | -20 | -14 | 0   |

- For each state **randomly choose 1 action**
- Numbers in states represent **expected values of states**
- Following a random policy, when starting from lower left corner, on **average 22 transitions** before reaching terminal state

Value function of **optimal** policy

|    |    |    |    |
|----|----|----|----|
| 0  | -1 | -2 | -3 |
| -1 | -2 | -3 | -2 |
| -2 | -3 | -2 | -1 |
| -3 | -2 | -1 | 0  |

Optimal value function

Optimal policy

- Value of state at lower left corner is -3
- Takes only 3 transitions to reach terminal state
- Given optimal value function, trivial to extract optimal policy

# Q-Learning

- Finds mapping of **state-action pairs** to “Q-values”
  - Vs. mapping from **states** to state values (Value iteration)
- In each state, each action is associated with a Q-value,  $Q(s_t, a_t)$
- Q-value - Expected future total reward
  - **Sum of the reinforcements** (possibly discounted) received when performing the **associated action** and **following the given policy** thereafter
- Optimal Q-value,  $Q^\pi(s, a)$ , is the sum of reinforcements received when performing associated action and following **optimal policy** thereafter.
- Value of state: **Maximum Q-value** in given state
- $$Q(s_t, a_t) = r(s_t, a_t) + \gamma \max_{a_{t+1}} Q(s_{t+1}, a_{t+1})$$
 Bellman equation for Q-learning

$$BQ^\pi(s, a) =$$

## Value Function

- Q-value function gives expected future total reward

- from state and action  $(s, a)$
  - under policy  $\pi$
  - with discount factor  $\gamma \in (0, 1)$

$$Q^\pi(s, a) = \mathbb{E} [r_{t+1} + \gamma r_{t+2} + \gamma^2 r_{t+3} + \dots | s, a]$$

- Show how good current policy

- Value functions can be defined using Bellman equation

$$Q^\pi(s, a) = \mathbb{E}_{s', a'} [r + \gamma Q^\pi(s', a') | s, a]$$

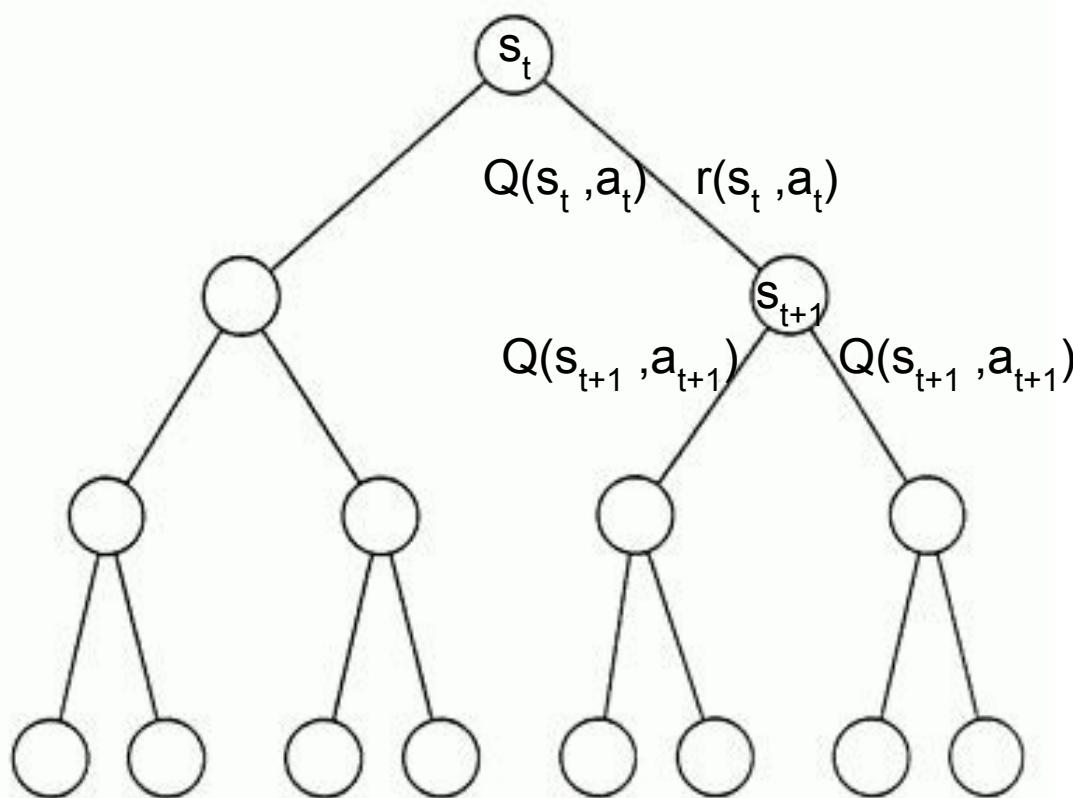

- Bellman backup operator

$$B^\pi Q(s, a) = \mathbb{E}_{s', a'} [r + \gamma Q^\pi(s', a') | s, a] \quad Q, B^\pi Q, (B^\pi)^2 Q, (B^\pi)^3 Q, \dots \rightarrow Q^\pi$$

# Bellman Backup Operator

$$B^\pi Q(s, a) = E_{s', a'}[r + \gamma Q^\pi(s', a')|s, a]$$

$$Q, B^\pi Q, (B^\pi)^2 Q, (B^\pi)^3 Q, \dots \rightarrow Q^\pi$$

- Lookup table to represent Q-function
- To update prediction  $Q(s_t, a_t)$ :
  - Perform  $a_t$ , causing transition to  $s_{t+1}$  and return  $r(s_t, a_t)$ .
- Only need to find **max** Q-value in **new state** to update Q-value for action just performed.
- After many updates, Q-value for  $a_t$  **converges to expected sum** of all reinforcements received when performing  $a_t$  and following optimal policy thereafter.

## Value Function

- For optimal Q-value function  $Q^*(s, a) = \max_{\pi} Q^\pi(s, a)$ , then policy function is deterministic, the Bellman equation becomes:

$$Q^*(s, a) = \mathbb{E}_{s'} \left[ r + \gamma \max_{a'} Q^*(s', a') \mid s, a \right]$$

$$B^\pi Q(s, a) = E_{s'} [r + \gamma \max_{a'} Q^\pi(s', a') | s, a]$$

$$Q, BQ, B^2Q, \dots \rightarrow Q^*$$

NEXT - We will discuss about Deep Reinforcement Learning

# Deep Q-Learning

- Wait before getting into Deep Q Learning
- Let's discuss Q-Learning

## Q Learning Recap

$A = \{1, \dots, K\}$  set of actions

$r_t$  = reward received at time step t

$s_t = x_1, a_1, x_2, \dots, a_{t-1}, x_t$

$s_t$  is the state at time step t

*don't be confused with  $x_t$ ,  $s_t$*

$\gamma$  = discount factor per time-step [  $0 < \gamma < 1$  ]

Future *discounted return* at time t

$$R_t = \sum_{t'=t}^T \gamma^{t'-t} r_{t'}$$

optimal action-value function  $Q^*(s, a)$

$$Q^*(s, a) = \max_{\pi} \mathbb{E}[R_t | s_t = s, a_t = a, \pi]$$

*The optimal action-value function  $Q^*(s, a)$  as the maximum expected return achievable by following any strategy, after seeing some sequence  $s$  and then taking some action  $a$ .*

*where  $\pi$  is a policy mapping sequences to actions (or distributions over actions)*

## Bellman Equation

The optimal action-value function obeys an important identity known as the Bellman equation

$$Q^*(s, a) = \mathbb{E}_{s' \sim \mathcal{E}} \left[ r + \gamma \max_{a'} Q^*(s', a') \middle| s, a \right]$$

The basic idea behind many reinforcement learning algorithms is to estimate the action-value function, by using the Bellman equation as an iterative update

$$Q_{i+1}(s, a) = \mathbb{E} [r + \gamma \max_{a'} Q_i(s', a') | s, a].$$

Such value iteration algorithms converge to the optimal action-value function,  
 $Q_i \rightarrow Q^*$  as  $i \rightarrow \infty$

$$\text{New } Q(s, a) = Q(s, a) + \alpha [R(s, a) + \gamma \max Q'(s', a') - Q(s, a)]$$

New Q value for that state and that action

Current Q value

Reward for taking that action at that state

Learning Rate

Discount rate

Maximum expected future reward given the new  $s'$  and all possible actions at that new state

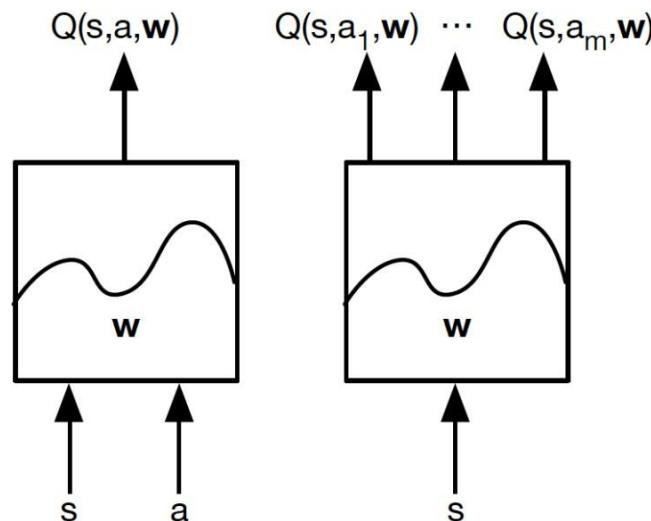

You can use different algorithm like

- Monte Carlo
- TD , TD (0), TD ( lambda )

# Deep Q-Learning

- Represent value function by Q-network

$$Q(s, a, \mathbf{w}) \approx Q^*(s, a)$$

# Deep Q-Learning

- Optimal Q-values should obey Bellman equation

$$Q^*(s, a) = \mathbb{E}_{s'} \left[ r + \gamma \max_{a'} Q(s', a')^* \mid s, a \right]$$

- Treat right-hand side as target network, given  $(s, a, r, s')$ , optimize MSE loss via SGD:

$$l = \left( r + \gamma \max_a Q(s', a, \mathbf{w}) - Q(s, a, \mathbf{w}) \right)^2$$

## Loss function

Loss: (target - predicted) ,  $y_i$  is target here

$$L_i(\theta_i) = \mathbb{E}_{s,a \sim \rho(\cdot)} [(y_i - Q(s, a; \theta_i))^2]$$

where  $y_i = \mathbb{E}_{s' \sim \mathcal{E}} [r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) | s, a]$

Gradient:

$$\nabla_{\theta_i} L_i(\theta_i) = \mathbb{E}_{s,a \sim \rho(\cdot); s' \sim \mathcal{E}} \left[ \left( r + \gamma \max_{a'} Q(s', a'; \theta_{i-1}) - Q(s, a; \theta_i) \right) \nabla_{\theta_i} Q(s, a; \theta_i) \right]$$

Target Y

notice the  
weights

$$Q(s', a'; \theta_{i-1})$$

Predicted  
Y\_hat

notice the  
weights

$$Q(s, a; \theta_i)$$

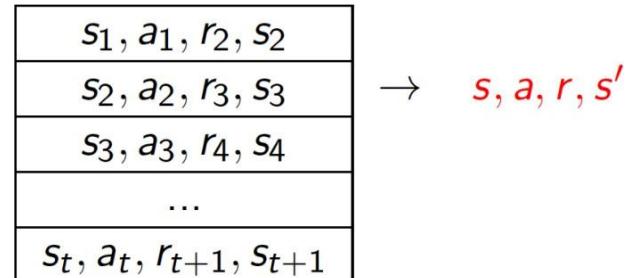

## What are some problems here ?

But diverges using neural networks due  
to:

- Correlations between samples
- Non-stationary targets

# Deep Q-Learning

Experience Replay: remove correlations, build data-set from agent's own experience

- Sample experiences from data-set and apply update

$$l = \left( r + \gamma \max_{a'} Q(s', a', \mathbf{w}^-) - Q(s, a, \mathbf{w}) \right)^2$$

- To deal with non-stationarity,
  - target parameters is fixed,
  - or use a separate Q\_network for target and predicted which is called **Double DQN**

## Deep Q-learning with Experience Replay

---

**Algorithm 1** Deep Q-learning with Experience Replay

---

Initialize replay memory  $\mathcal{D}$  to capacity  $N$

Initialize action-value function  $Q$  with random weights

**for** episode = 1,  $M$  **do**

    Initialise sequence  $s_1 = \{x_1\}$  and preprocessed sequenced  $\phi_1 = \phi(s_1)$

**for**  $t = 1, T$  **do**

        With probability  $\epsilon$  select a random action  $a_t$

        otherwise select  $a_t = \max_a Q^*(\phi(s_t), a; \theta)$

        Execute action  $a_t$  in emulator and observe reward  $r_t$  and image  $x_{t+1}$

        Set  $s_{t+1} = s_t, a_t, x_{t+1}$  and preprocess  $\phi_{t+1} = \phi(s_{t+1})$

        Store transition  $(\phi_t, a_t, r_t, \phi_{t+1})$  in  $\mathcal{D}$

        Sample random minibatch of transitions  $(\phi_j, a_j, r_j, \phi_{j+1})$  from  $\mathcal{D}$

        Set  $y_j = \begin{cases} r_j & \text{for terminal } \phi_{j+1} \\ r_j + \gamma \max_{a'} Q(\phi_{j+1}, a'; \theta) & \text{for non-terminal } \phi_{j+1} \end{cases}$

        Perform a gradient descent step on  $(y_j - Q(\phi_j, a_j; \theta))^2$  according to equation 3

**end for**

**end for**

---

# Double DQNs

- To handle the problem of over estimation of Q-Values
- *how are we sure that the best action of the next state is the action with highest Q-Value*
- The solution is
  - use our DQN network to select what is the best action to take for the next state
    - (action with the highest Q-Value)
  - use our target network to calculate the target the target Q value of taking that action at the next state.

$$Q(s, a) = r(s, a) + \gamma Q(s', \underbrace{\text{argmax}_a Q(s', a)}_{\text{DQN Network choose action for next state}})$$

---

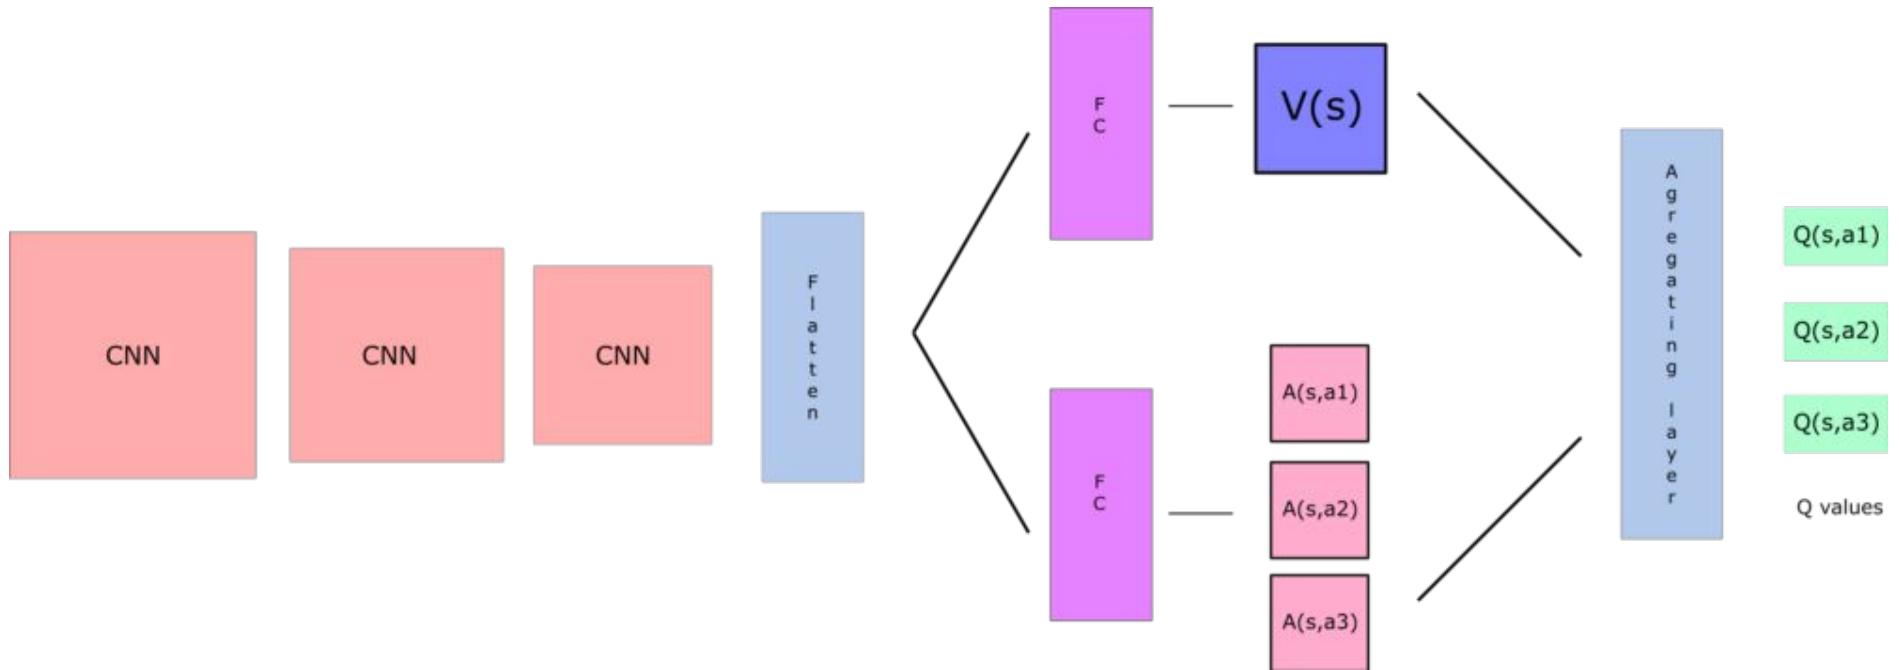

TD target

Target network calculates the Q value of taking that action at that state

# Dueling DQN (aka DDQN)

- Remember that Q-values correspond **to how good it is to be at that state and taking an action at that state  $Q(s,a)$ .**
- So we can decompose  $Q(s,a)$  as the sum of:
  - **$V(s)$ :** the value of being at that state
  - **$A(s,a)$ :** the advantage of taking that action at that state (how much better is to take this action versus all other possible actions at that state).

$$Q(s, a) = A(s, a) + V(s)$$

# Prioritized Experience Replay

- Prioritized Experience Replay (PER) was introduced in 2015 by [Tom Schaul](#). The idea is that some experiences may be more important than others for our training, but might occur less frequently.
- We want to take in priority **experience where there is a big difference between our prediction and the TD target, since it means that we have a lot to learn about it.**
- We use the absolute value of the magnitude of our TD error:

$$p_t = \underline{|\delta_t|} + \underline{e}$$

Magnitude of our  
TD error

Constant assures  
that no experience  
has 0 probability to  
be taken.

# Prioritized Experience Replay cont..

But how are we going to sample from the ReplayMemory Dataset

we can't just do greedy prioritization,  
because it will lead to always training the same experiences (that have big priority),  
and thus over-fitting.

# Stochastic prioritization

$$P(i) = \frac{p_i}{\sum_k p_k^a}$$

Priority value

Normalized by all priority values in Replay Buffer

The diagram shows the formula for stochastic prioritization. A green arrow points from the term  $p_i$  to its position in the numerator. A red arrow points from the term  $\sum_k p_k^a$  to its position in the denominator. The variable  $a$  is shown in a small blue box above each  $p_k$  term in the denominator.

Hyperparameter used to reintroduce some randomness in the experience selection for the replay buffer

If  $a = 0$  pure uniform randomness

If  $a = 1$  only select the experiences with the highest priorities

## Bias Correction - during weight updates

As consequence, during each time step, we will get a batch of samples with this probability distribution and train our network on it.

But, we still have a problem here. Remember that with normal Experience Replay, we use a stochastic update rule. As a consequence, the **way we sample the experiences must match the underlying distribution they came from.**

When we do have normal experience, we select our experiences in a normal distribution—simply put, we select our experiences randomly. There is no bias, because each experience has the same chance to be taken, so we can update our weights normally.

**But**, because we use priority sampling, purely random sampling is abandoned. As a consequence, we introduce bias toward high-priority samples (more chances to be selected).

## Importance sampling weights (IS)

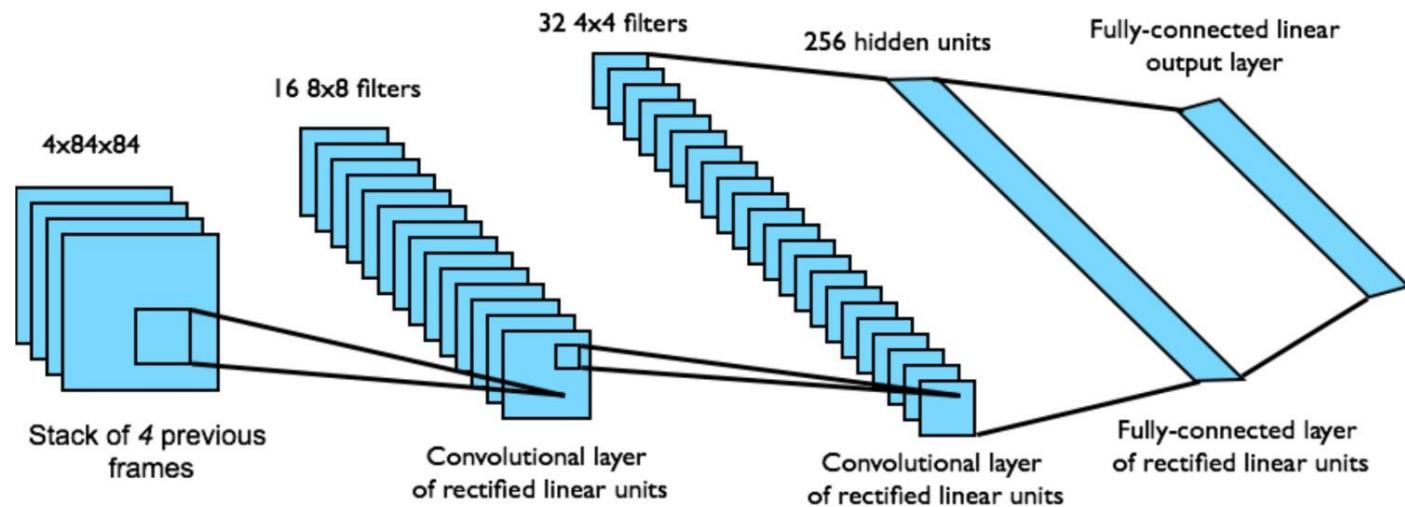

$$\left( \frac{1}{N} \cdot \frac{1}{P(i)} \right)^b$$

**Replay Buffer Size**      **Sampling probability**

Controls how much the IS w affect learning.  
Close to 0 at the beginning of learning and annealed up to 1 over the duration of training because **these weights are more important in the end of learning when our q values begin to converge**

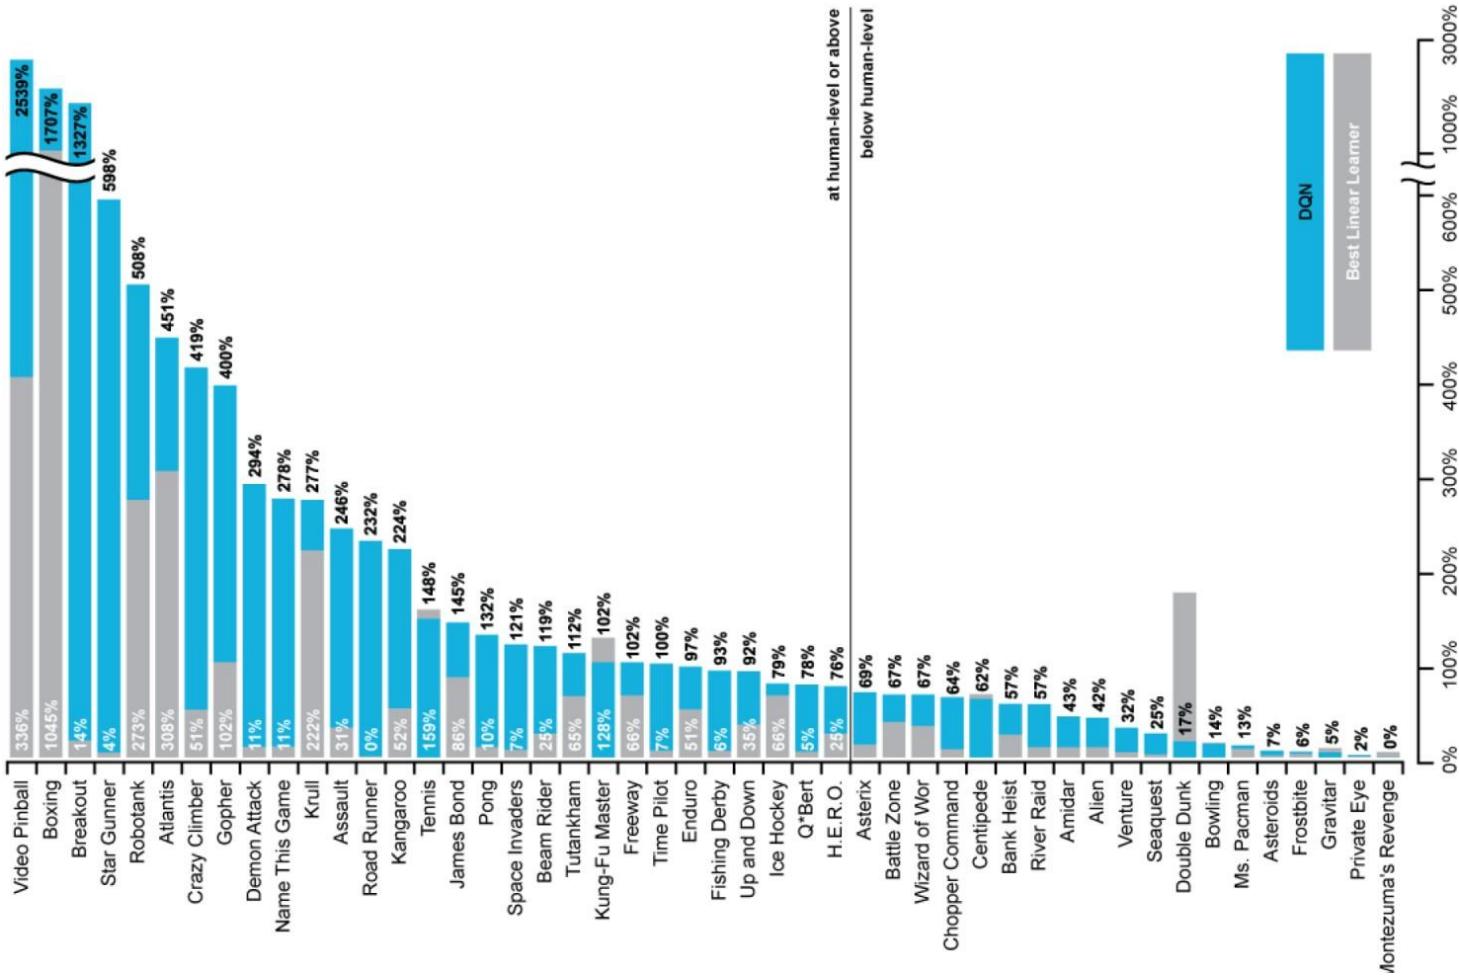

1. The weights corresponding to high-priority samples have very little adjustment (because the network will see these experiences many times), whereas those corresponding to low-priority samples will have a full update
2. The role of **b** is to control how much these importance sampling weights affect learning. In practice, the b parameter is annealed up to 1 over the duration of training, because these weights are more important **in the end of learning when our q values begin to converge.**

# Policy based - Deep RL

- Policy Gradient

## Policy Gradient in a Nutshell

- In policy-based methods, instead of learning a value function that tells us what is the expected sum of rewards given a state and an action, we learn directly the policy function that maps state to action.
- It means that we directly try to optimize our policy function  $\pi$  without worrying about a value function. We'll directly parameterize  $\pi$  (select an action without a value function).

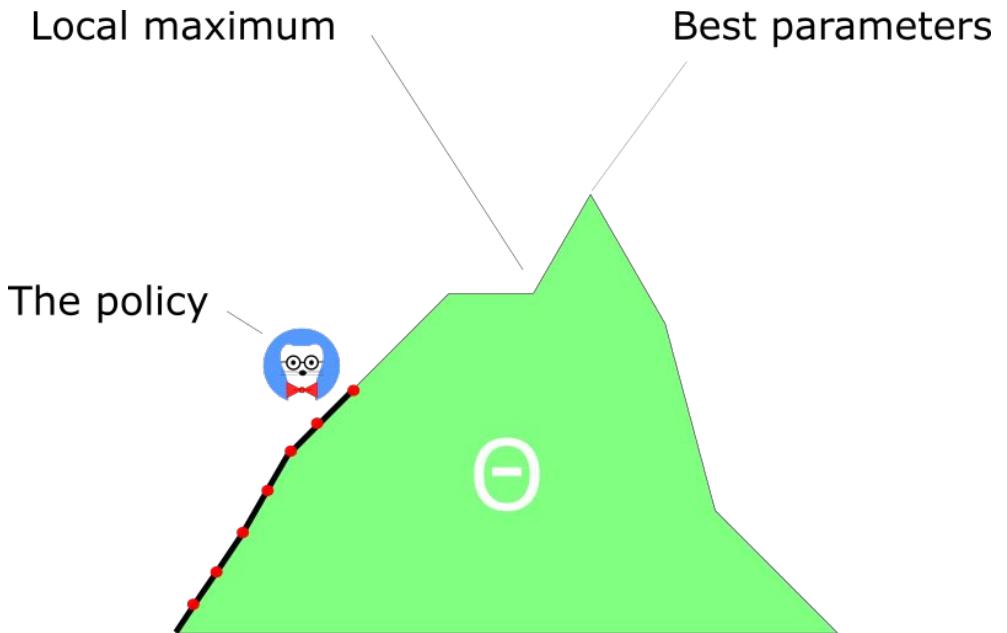

### Two types of policy

A policy can be either deterministic or stochastic.

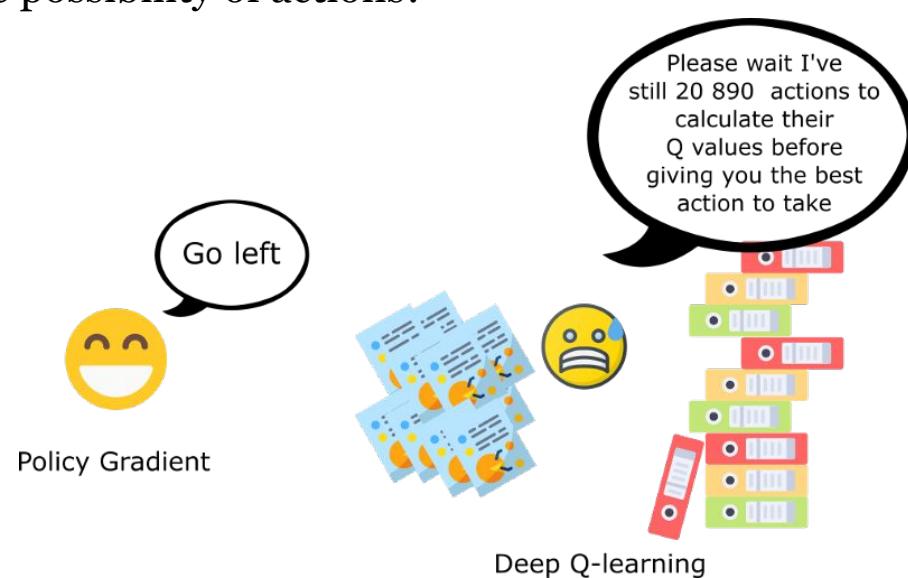

We will explore stochastic policy

## Main Advantages of Policy Gradient

- **Convergence**

- **Policy gradients are more effective in high dimensional action spaces**
  - For Deep Q-Learning, what if we have an infinite possibility of actions?

## Differences

1. Naturally, **Policy gradients** have one big disadvantage.
  - a. A lot of the time, they **converge on a local maximum** rather than on the global optimum.
2. Instead of **Deep Q-Learning**, which always tries to reach the maximum, policy gradients **converge slower**, step by step.
  - a. They can **take longer to train**.

# Policy Gradients

Formally, let's define a class of parametrized policies:  $\Pi = \{\pi_\theta, \theta \in \mathbb{R}^m\}$

For each policy, define its value:

$$J(\theta) = \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t r_t | \pi_\theta \right]$$

We want to find the optimal policy  $\theta^* = \arg \max_{\theta} J(\theta)$

How can we do this?

Gradient ascent on policy parameters!

# REINFORCE algorithm

Mathematically, we can write:

$$\begin{aligned} J(\theta) &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)] \\ &= \int_{\tau} r(\tau)p(\tau; \theta)d\tau \end{aligned}$$

Where  $r(\tau)$  is the reward of a trajectory  $\tau = (s_0, a_0, r_0, s_1, \dots)$

# REINFORCE algorithm

Expected reward:

$$\begin{aligned} J(\theta) &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)] \\ &= \int_{\tau} r(\tau)p(\tau; \theta)d\tau \end{aligned}$$

Now let's differentiate this:

$$\nabla_{\theta} J(\theta) = \int_{\tau} r(\tau)\nabla_{\theta}p(\tau; \theta)d\tau$$

Intractable! Gradient of an expectation is problematic when p depends on  $\theta$

However, we can use a nice trick:

$$\nabla_{\theta}p(\tau; \theta) = p(\tau; \theta) \frac{\nabla_{\theta}p(\tau; \theta)}{p(\tau; \theta)} = p(\tau; \theta)\nabla_{\theta}\log p(\tau; \theta)$$

If we inject this back:

$$\begin{aligned} \nabla_{\theta}J(\theta) &= \int_{\tau} (r(\tau)\nabla_{\theta}\log p(\tau; \theta)) p(\tau; \theta)d\tau \\ &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau)\nabla_{\theta}\log p(\tau; \theta)] \end{aligned}$$

Can estimate with  
Monte Carlo sampling

# REINFORCE algorithm

$$\begin{aligned}\nabla_{\theta} J(\theta) &= \int_{\tau} (r(\tau) \nabla_{\theta} \log p(\tau; \theta)) p(\tau; \theta) d\tau \\ &= \mathbb{E}_{\tau \sim p(\tau; \theta)} [r(\tau) \nabla_{\theta} \log p(\tau; \theta)]\end{aligned}$$

Can we compute those quantities without knowing the transition probabilities?

We have:  $p(\tau; \theta) = \prod_{t \geq 0} p(s_{t+1} | s_t, a_t) \pi_{\theta}(a_t | s_t)$

Thus:  $\log p(\tau; \theta) = \sum_{t \geq 0} \log p(s_{t+1} | s_t, a_t) + \log \pi_{\theta}(a_t | s_t)$

And when differentiating:  $\nabla_{\theta} \log p(\tau; \theta) = \sum_{t \geq 0} \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

Doesn't depend on  
transition probabilities!

Therefore when sampling a trajectory  $\tau$ , we can estimate  $J(\theta)$  with

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# Intuition

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

## Interpretation:

- If  $r(\tau)$  is high, push up the probabilities of the actions seen
- If  $r(\tau)$  is low, push down the probabilities of the actions seen

Might seem simplistic to say that if a trajectory is good then all its actions were good. **But in expectation, it averages out!**

However, this also suffers from high variance because credit assignment is really hard. Can we help the estimator?

# Variance reduction

Gradient estimator:  $\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} r(\tau) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$

**First idea:** Push up probabilities of an action seen, only by the cumulative future reward from that state

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} r_{t'} \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

**Second idea:** Use discount factor  $\gamma$  to ignore delayed effects

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t' - t} r_{t'} \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# Variance reduction: Baseline

**Problem:** The raw value of a trajectory isn't necessarily meaningful. For example, if rewards are all positive, you keep pushing up probabilities of actions.

**What is important then?** Whether a reward is better or worse than what you expect to get

**Idea:** Introduce a baseline function dependent on the state.  
Concretely, estimator is now:

$$\nabla_{\theta} J(\theta) \approx \sum_{t \geq 0} \left( \sum_{t' \geq t} \gamma^{t'-t} r_{t'} - b(s_t) \right) \nabla_{\theta} \log \pi_{\theta}(a_t | s_t)$$

# How to choose the baseline?

A better baseline: Want to push up the probability of an action from a state, if this action was better than the **expected value of what we should get from that state**.

Q: What does this remind you of?

A: Q-function and value function!

Intuitively, we are happy with an action  $a_t$  in a state  $s_t$  if  $Q^\pi(s_t, a_t) - V^\pi(s_t)$  is large. On the contrary, we are unhappy with an action if it's small.

# Actor-Critic Algorithm

Initialize policy parameters  $\theta$ , critic parameters  $\phi$

**For** iteration=1, 2 ... **do**

    Sample m trajectories under the current policy

$$\Delta\theta \leftarrow 0$$

**For** i=1, ..., m **do**

**For** t=1, ..., T **do**

$$A_t = \sum_{t' \geq t} \gamma^{t'-t} r_t^i - V_\phi(s_t^i)$$

$$\Delta\theta \leftarrow \Delta\theta + A_t \nabla_\theta \log(a_t^i | s_t^i)$$

$$\Delta\phi \leftarrow \sum_i \sum_t \nabla_\phi ||A_t^i||^2$$

$$\theta \leftarrow \alpha \Delta\theta$$

$$\phi \leftarrow \beta \Delta\phi$$

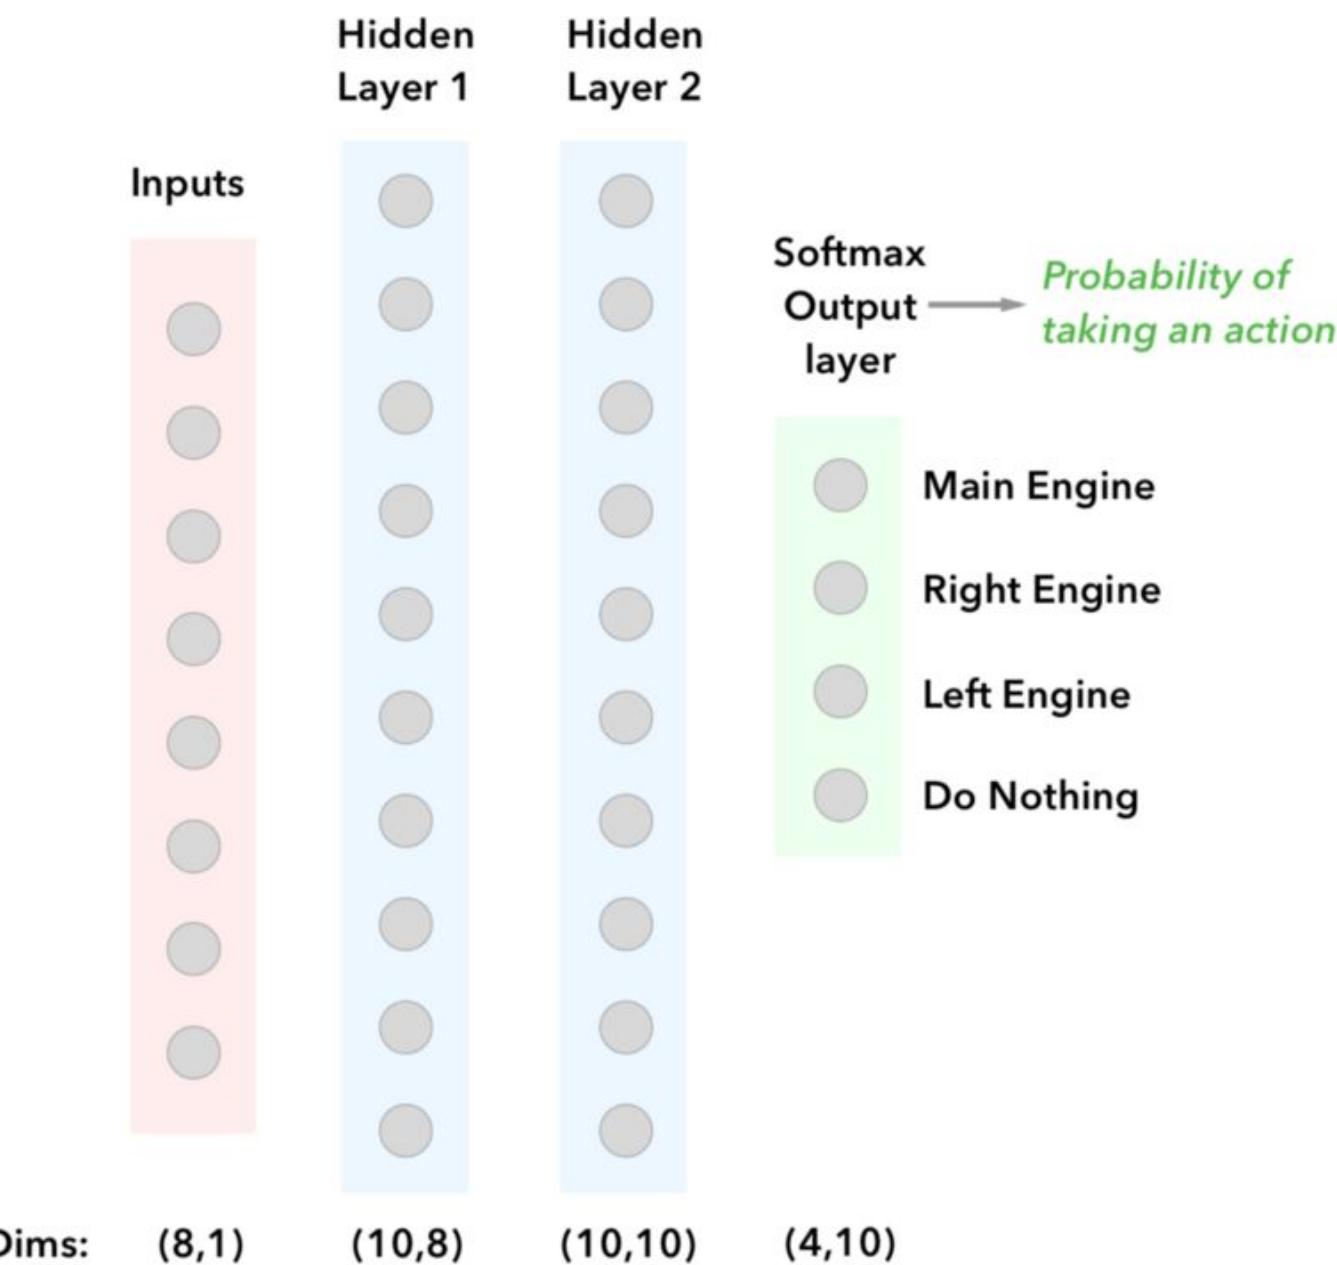

**End for**

# Deep Policy Network

- Represent policy by deep neural network  
that

$$\max^C E_{B \sim G(B|C,H)}[r(a)|\theta, s]$$

- Ideas: given a bunch of trajectories,
  - Make the good trajectories/action more probable
  - Push the actions towards good actions

# Article Summarization

Text summarization is the process of automatically generating natural language summaries from an input document while retaining the important points.

- extractive summarization
- abstractive summarization

## A Deep Reinforced Model for Abstractive Summarization

Given  $x = \{x_L, x_M, \dots, x_O\}$  represents the sequence of input (article) tokens,  
 $y = \{y_L, y_M, \dots, y_R\}$ , the sequence of output (summary) tokens

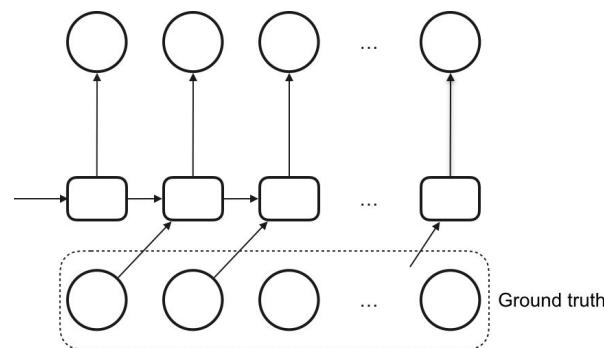

Paulus et. al.

# A Deep Reinforced Model for Abstractive Summarization

The maximum-likelihood training objective:

$$L_{ml} = - \sum_{t=1}^{n'} \log p(y_t^* | y_1^*, \dots, y_{t-1}^*, x)$$

Training with teacher forcing algorithm.

*Paulus et. al.*

## A Deep Reinforced Model for Abstractive Summarization

There is discrepancy between training and test performance, because

- exposure bias
- potentially valid summaries
- metric difference

*Paulus et. al.*

## A Deep Reinforced Model for Abstractive Summarization

Using reinforcement learning framework, learn a policy that maximizes a specific discrete metric.

Action:  $u_T \in [copy, generate]$  and word  $y^H_T$

State: hidden states of encoder and previous outputs

Reward: ROUGH score

$$L_{rl} = (r(\hat{y}) - r(y^s)) \sum_{t=1}^{n'} \log p(y_t^s | y_1^s, \dots, y_{t-1}^s, x)$$

Where  $p(y_T^H | y^H, \dots, y_{T-1}^H, x) = p(u_T = copy | y^H, \dots, y_{T-1}^H, x, u_T = copy) + p(u_T = generate | y^H, \dots, y_{T-1}^H, x, u_T = generate)$

# Text Question Answering

---

**Passage:** Tesla later approached Morgan to ask for more funds to build a more powerful transmitter. When asked where all the money had gone, Tesla responded by saying that he was affected by the **Panic of 1901**, which he (Morgan) had caused. Morgan was shocked by the reminder of his part in the stock market crash and by Tesla's breach of contract by asking for more funds. Tesla wrote another plea to Morgan, but it was also fruitless. Morgan still owed Tesla money on the original agreement, and Tesla had been facing foreclosure even before construction of the tower began.

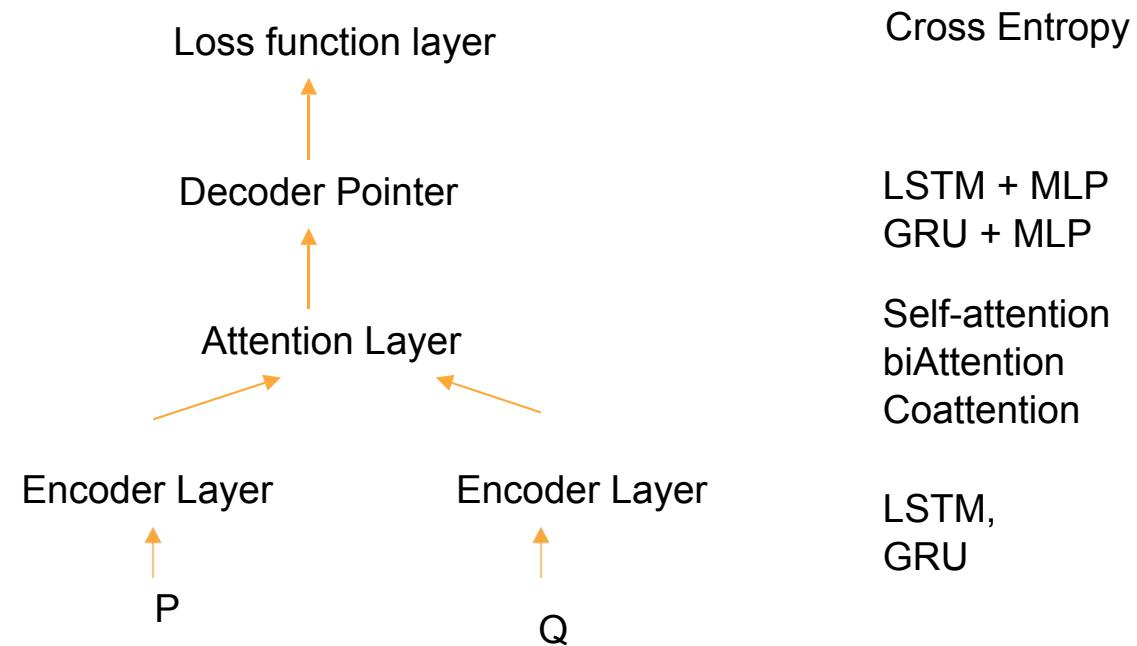

**Question:** On what did Tesla blame for the loss of the initial money?

**Answer:** **Panic of 1901**

---

*Example from SQuAD dataset*

# Text Question Answering

## DCN+: MIXED OBJECTIVE AND DEEP RESIDUAL COATTENTION FOR QUESTION ANSWERING

Constraints of Cross-Entropy loss:

P: “Some believe **that the Golden State Warriors team of 2017** is one of the greatest teams in NBA history,...”

Q: “which team is considered to be one of the greatest teams in NBA history”

GT: “**the Golden State Warriors team of 2017**”

Ans1: “**Warriors**” Ans2: “**history**”

## DCN+: MIXED OBJECTIVE AND DEEP RESIDUAL COATTENTION FOR QUESTION ANSWERING

To address this, we introduce F1 score as extra objective combining with traditional cross entropy loss:

$$\begin{aligned} l_{rl}(\Theta) &= -\mathbb{E}_{\hat{\tau} \sim p_\tau}[R(s, e, \hat{s}_T, \hat{e}_T; \Theta)] \\ &\approx -\mathbb{E}_{\hat{\tau} \sim p_\tau}[F_1(\text{ans}(\hat{s}_T, \hat{e}_T), \text{ans}(s, e)) - F_1(\text{ans}(s_T, e_T), \text{ans}(s, e))] \end{aligned}$$

$$\begin{aligned} \nabla_\Theta l_{rl}(\Theta) &= -\nabla_\Theta(\mathbb{E}_{\hat{\tau} \sim p_\tau}[R]) \\ &= -\mathbb{E}_{\hat{\tau} \sim p_\tau}[R \nabla_\Theta \log p_\tau(\tau; \Theta)] \end{aligned}$$

Not necessary for variable length.

# Dialogue generation

What is it?

- Generating responses for conversational agents.

A: Where are you going? (1)

B: I'm going to the restroom. (2)

A: how old are you? (1)

B: I'm 16. (2)

# Dialogue generation

## Training data

- OpenSubtitles dataset -- <https://www.opensubtitles.org/>
- A dialogue with 2 agents, p and q, will look as such:
  - $p_1, q_1, p_2, q_2, \dots, p_i, q_i$
  - Input:  $[p_i, q_i]$
  - Output:  $p_{i+1}$

# Dialogue generation

## Baseline model

- LSTM sequence-to-sequence (SEQ2SEQ)

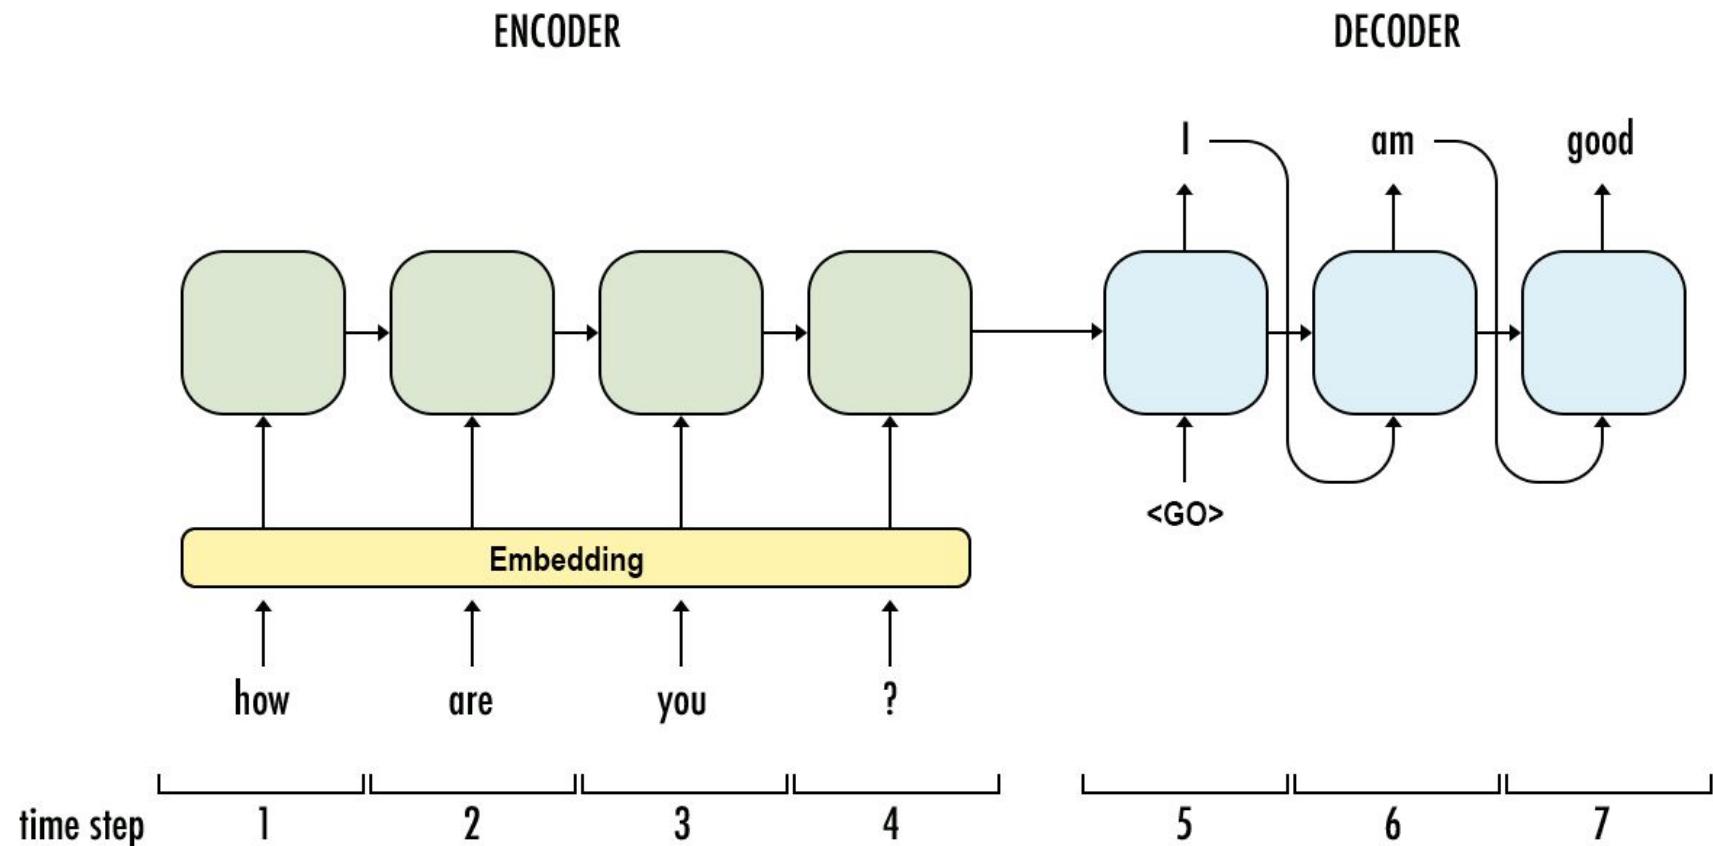

Image credits: <https://towardsdatascience.com/sequence-to-sequence-model-introduction-and-concepts-44d9b41cd42d>

# Dialogue generation

## Baseline model limitations

- 1) SEQ2SEQ models tend to generate highly generic responses, e.g. I don't know
- 2) Getting stuck in an infinite loop of repetitive responses

---

### **Baseline mutual information model (Li et al. 2015)**

---

A: Where are you going? (1)  
B: I'm going to the restroom. (2)  
A: See you later. (3)  
B: See you later. (4)  
A: See you later. (5)  
B: See you later. (6)

...

...

---

A: how old are you? (1)  
B: I'm 16. (2)  
A: 16? (3)  
B: I don't know what you are talking about. (4)  
A: You don't know what you are saying. (5)  
B: I don't know what you are talking about . (6)  
A: You don't know what you are saying. (7)

...

# Dialogue generation

## Baseline model limitations

- 1) SEQ2SEQ models tend to generate highly generic responses, e.g. I don't know
- 2) Getting stuck in an infinite loop of repetitive responses

To solve these, the model needs:

- Integrate developer-defined rewards that better mimic the true goal of chatbot development
- Model the long term influence of a generated response in an ongoing dialogue

# Dialogue generation

## RL model

- State:  $[p_i, q_i]$
  - Action: Sequence to be generated. The action space is infinite.
  - Reward: Ease of answering, Information Flow, Semantic Coherence
- 
- SEQ2SEQ model is similar to a policy gradients model -- it generates actions based on the state
  - SEQ2SEQ optimizes parameters based on MLE
  - RL further optimizes the parameters based on rewards

# Dialogue generation

## RL reward - Ease of answering

- A response generated by the model should be easy to respond to
- Responses which are hard to answer to -> more likely to be responded to with a ‘dull response’
- ‘Dull response’?
  - E.g. ‘I have no idea’

$$r_1 = -\frac{1}{N_{\mathbb{S}}} \sum_{s \in \mathbb{S}} \frac{1}{N_s} \log p_{\text{seq2seq}}(s|a)$$

- Higher likelihood of a dull response -> lower reward

# Dialogue generation

## RL reward - Information Flow

- New information should be contributed at each turn
- Penalize semantic similarity between consecutive turns from the same agent

$$r_2 = -\log \cos(h_{p_i}, h_{p_{i+1}}) = -\log \cos \frac{h_{p_i} \cdot h_{p_{i+1}}}{\|h_{p_i}\| \|h_{p_{i+1}}\|}$$

$h_{p_i}$  and  $h_{p_{i+1}}$  are the hidden representations obtained from the encoder for 2 consecutive turns of agent p

- Higher cosine similarity  $\rightarrow$  lower reward

# Dialogue generation

## RL reward - Semantic coherence (Mutual Information)

- Avoid situations in which the generated replies are highly rewarded but are ungrammatical or not coherent
- Uses Mutual Information

$$r_3 = \frac{1}{N_a} \underbrace{\log p_{\text{seq2seq}}(a|q_i, p_i)}_{\text{Probability of generating action } a, \text{ given state } [p_i, q_i]} + \frac{1}{N_{q_i}} \underbrace{\log p_{\text{seq2seq}}^{\text{backward}}(q_i|a)}_{\text{Backward probability of generating the previous dialogue } q_i \text{ given action } a}$$

Probability of generating action  $a$ , given state  $[p_i, q_i]$

Backward probability of generating the previous dialogue  $q_i$  given action  $a$

- Lower Mutual Information score  $\rightarrow$  lower reward

# Dialogue generation

## RL reward - Combining 3 rewards

- Final reward is weighted sum of the 3 rewards

$$r(a, [p_i, q_i]) = \lambda_1 r_1 + \lambda_2 r_2 + \lambda_3 r_3$$

# Dialogue generation

## Putting everything together

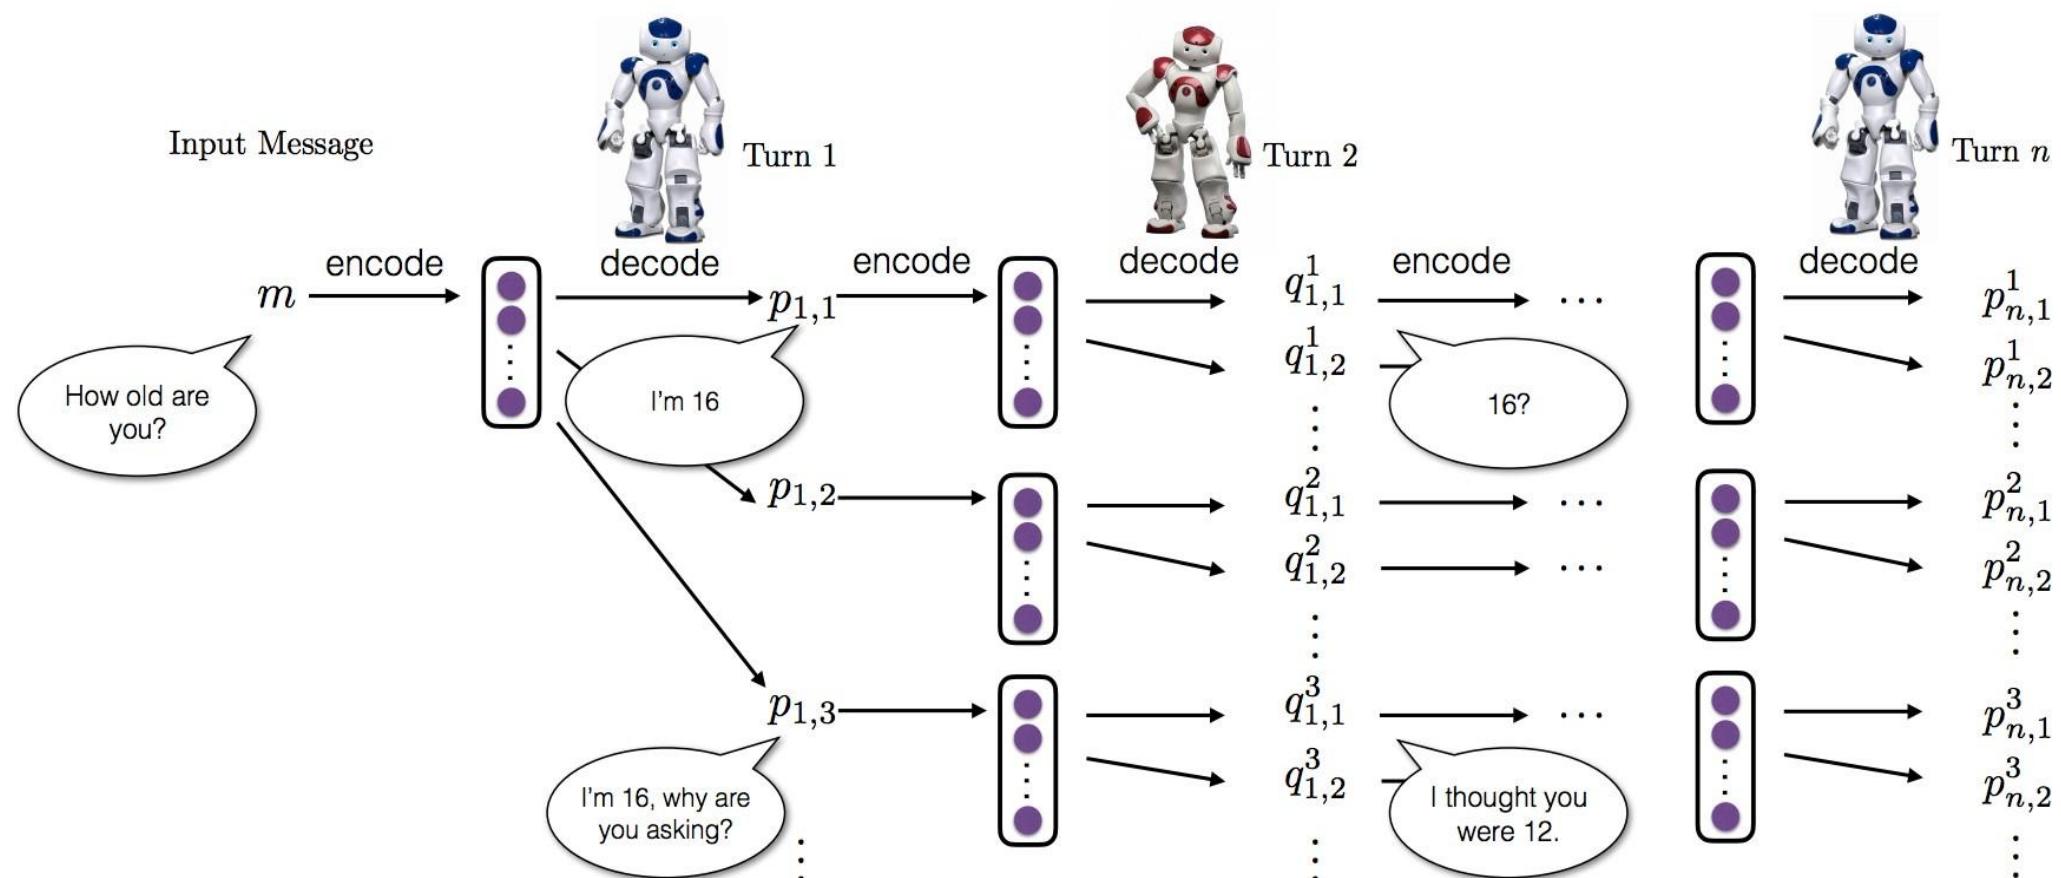

- 1) Supervised learning, training SEQ2SEQ model
  - a) Not good for initializing policy model, due to generic responses
- 2) Mutual Information for pre-training policy model
  - a) Initialize with model from (1)
  - b) For each data point, there's a MLE loss, and a Mutual Information Score (reward)
  - c) Use Curriculum Learning strategy, which optimizes for both

$$r_3 = \frac{1}{N_a} \log p_{\text{seq2seq}}(a|q_i, p_i) + \frac{1}{N_{q_i}} \log p_{\text{seq2seq}}^{\text{backward}}(q_i|a)$$

# Dialogue generation

## Dialogue Simulation between 2 agents

- Using the simulated turns and reward, maximize the expected future reward.

# Dialogue generation

## Results

| Model              | # of simulated turns |
|--------------------|----------------------|
| SEQ2SEQ            | 2.68                 |
| mutual information | 3.40                 |
| RL                 | 4.48                 |

| Setting                     | RL-win | RL-lose | Tie  |
|-----------------------------|--------|---------|------|
| single-turn general quality | 0.40   | 0.36    | 0.24 |
| single-turn ease to answer  | 0.52   | 0.23    | 0.25 |
| multi-turn general quality  | 0.72   | 0.12    | 0.16 |

| Input Message                    | Mutual Information Model                 | RL  |
|----------------------------------|--|---|
| How old are you?                 | I'm 16.                                  | I'm 16, why are you asking?               |
| What's your full name?           | I have no idea.                          | What's yours?                             |
| I don't want to go home tonight. | Really?                                  | Why?                                      |
| Do you have any feelings for me? | I don't know what you are talking about. | I don't want to hurt your feelings.       |
| How much time do you have here?  | Not long enough. Sorry, sir.             | Ten seconds.                              |
| Shall we get started?            | Of course!                               | Yes. We've got a lot of work to do here.  |
| Do you play football?            | No, i don't                              | Yes. I love football!                     |
| We'd have to talk to him.        | I mean, he's a good guy                  | About what ?                              |
| How come you never say it?       | Because I don't want to hurt you.        | I don't think it's a good idea to say it. |

# Dialogue generation

## Annex 1a - Mutual Information reward derivation (part 1)

- Mutual Information for previous sequence  $S$  and response  $T$

$$\log \frac{p(S, T)}{p(S)p(T)}$$

- MMI objective

$$\hat{T} = \arg \max_T \{ \log p(T|S) - \log p(T) \}$$

$$\hat{T} = \arg \max_T \{ \log p(T|S) - \lambda \log p(T) \}$$

$\lambda$  : controls the penalization for generic response

# Dialogue generation

## Annex 1b - Mutual Information reward derivation (part 2)

$$\hat{T} = \arg \max_T \{ \log p(T|S) - \lambda \log p(T) \}$$

$$\log p(T) = \log p(T|S) + \log p(S) - \log p(S|T)$$

$$\begin{aligned}\hat{T} &= \arg \max_T \{ (1 - \lambda) \log p(T|S) \\ &\quad + \lambda \log p(S|T) - \lambda \log p(S) \} \\ &= \arg \max_T \{ (1 - \lambda) \log p(T|S) + \lambda \log p(S|T) \}\end{aligned}$$

Consider  $S$  as  $(q_i, p_i)$ ,  $T$  as  $a$ , we can have

$$r_3 = \frac{1}{N_a} \log p_{\text{seq2seq}}(a|q_i, p_i) + \frac{1}{N_{q_i}} \log p_{\text{seq2seq}}^{\text{backward}}(q_i|a)$$
